

# Display property in CSS

The CSS display property is used to define the type of box used for an HTML element. The block value of the display property is used to create a block-level element, which takes up the full width available and forces a line break before and after the element. Here's an example of using the display:block value in an inline element:

without display block property

with display block property

# Display inline block in CSS

The `display: inline-block` property in CSS is used to make an element display as an inline-level block container.

When an element is set to `display: inline-block`, it will behave like an inline element in terms of being placed within the flow of text and not forcing a new line to start after it, but it will also behave like a block-level element in terms of being able to set a width and height, apply margins and paddings, and be positioned using the `position` property.

# Display-inline in CSS

The `display: inline` property in CSS is used to make an element display as an inline element, rather than a block-level element.

When an element is set to `display: inline`, it will not force a new line to start after it, and it will only take up as much width as necessary to display its contents. This is in contrast to a block-level element, which will take up the full width of its parent container and create a new line after it.
